

6502 DEBUGGER

Haley Whitman Alison Legge

Frazer Bayley Jeremy Brennan

Abdualziz AL-Heidous

CIS 422 - Dr. Faulk

Project is split into two deliverable parts

- I. MOS Technology 6502 Processor
- 2. Debugging Interface for 6502 Assembly

Requirements for 6502 Processor

- I. Accurately emulate the behavior of a 6502 processor.
- 2. Allow for third-party control of the processor.

Requirements for the debugging interface

- I. Allow for a user to input 6502 assembly
- 2. Allow for the user to view the results, and step through their inputted program.

PROJECT PLAN

Followed an iterative design, split between

- I. Creating the processor.
- 2. Creating the debugging interface.

We created the module design for the processor from Synertek and MOS Technology's 6502 Programming/Hardware manual.

We followed customer requests and typical debugging use-cases to design the debugging interface. Our documentation focused much more heavily on the debugging interface.

We have met all the customer requirements laid out for us, and documentation needed for the class. Deliverables are laid out in the following slides.

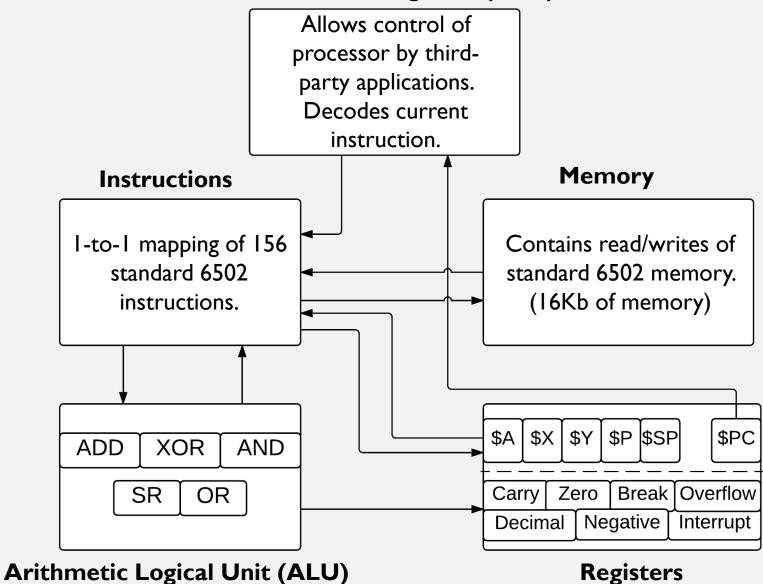

PROCESSOR DESIGN

Fairly typical design specification

Follows original dataflow of 6502 processor

Central Processing Unit (CPU)

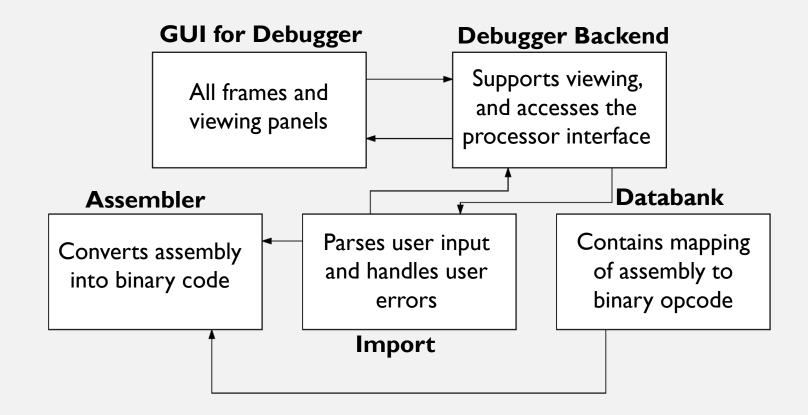

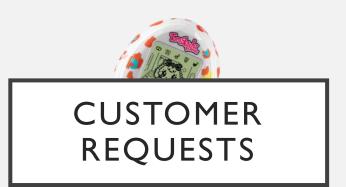

Fairly typical debugging interface, modeled after more retro-based debuggers for processors such as the Gameboy, where analyzing memory output is helpful.

Has to easily allow for further features.

Written completely separate from the processor

Three Main Points

- I. Wanted to be able to load any set of standard 6502 programs.
- 2. Be able to fully execute, or step through the program in a variety of ways.
- 3. Be able to easily view the processor changing line by line

Customer Iterations

- I.We continually presented the customer with the product, and received feedback on what to alter.
- 2. Multiple behavioral changes, involving controlling the flow of the processor.
- 3. Few interface changes.

Code Reviews

- I. All processor, and specific debugger module code have unit tests written for them. This allowed for regression testing.
- 2. Overall code behavior was done by running a suite of 6502 assembly programs. Processor behavior was compared with other 6502 emulators.

Documentation Reviews

I. Feedback was received for all documentation, and reviews were completed by two people per document, each focusing on specific aspects of the document.

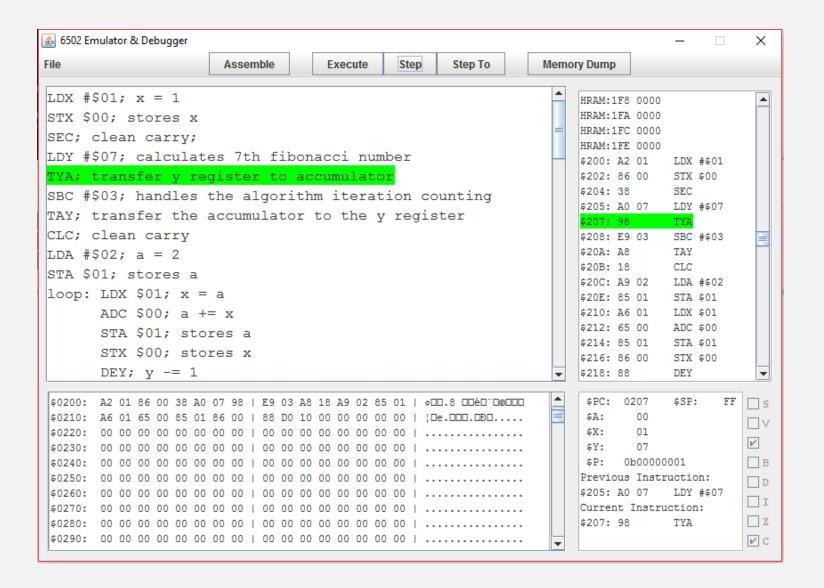

Documentation

- I. Documentation drafts were mostly on schedule. There were some issues with getting reviews implemented into the main documentation. This was addressed by doing more complete reviews after the initial review.
- 2. Needed a better way of organizing requests made for the documentation in the classroom.

Coding

- I. We had a great module structure, allowed for a lot of concurrent work, and was very effective for our team.
- 2. We employed heavy use of pair-programming, which greatly helped in understanding the flow of the processor.

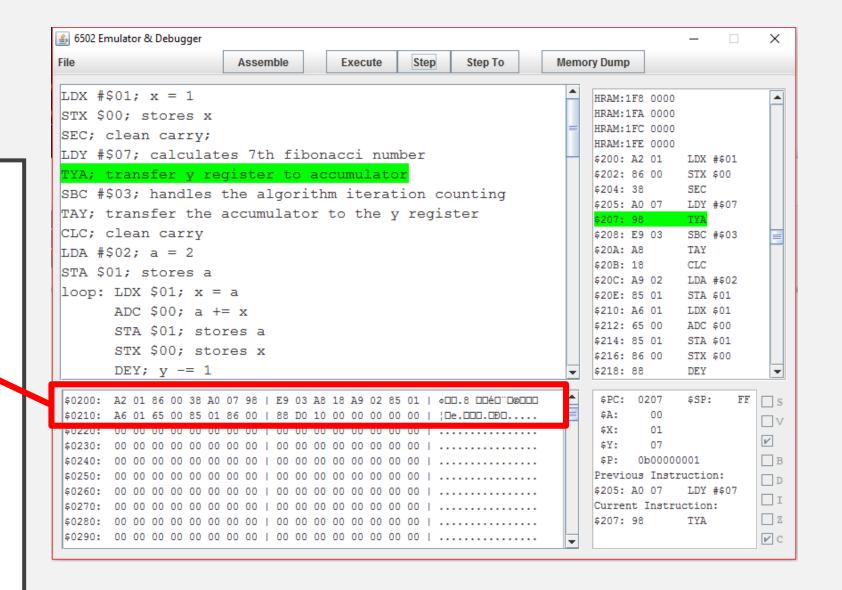

Memory gets stored, and updated with every CPU cycle. This is easily viewed in base-16, split every 16 bytes.

The ASCII memory representation is shown on the left.

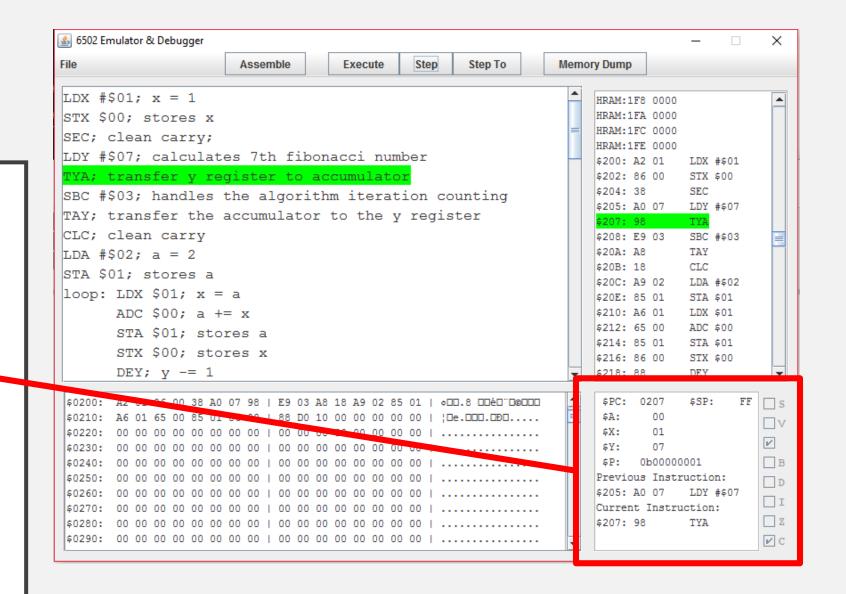

All register values are updated at every cycle (Shown in base-16).

The previous and currently executed instruction are also shown

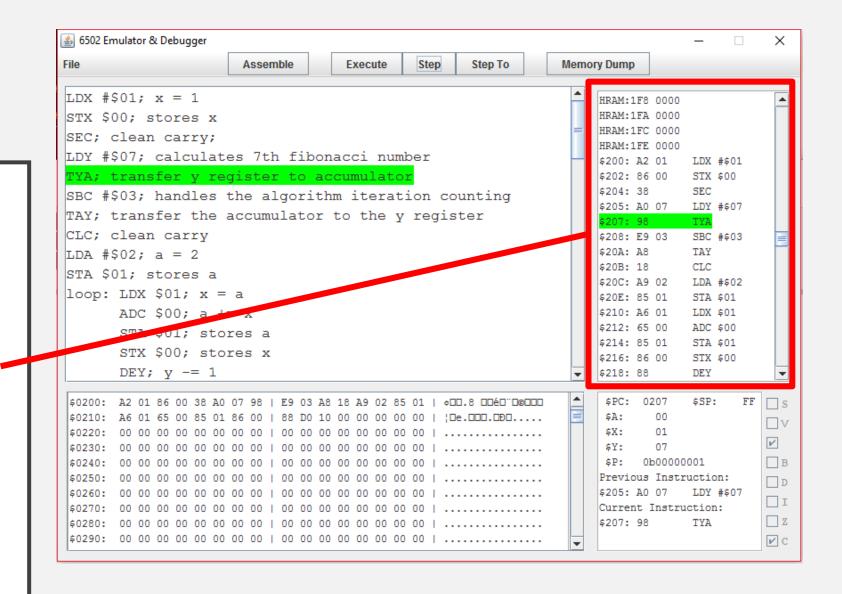

Register flags are visualized with checkboxes, if they are currently set.

A more detailed look at the processor's Zero page, High-Index Ram, and starting ROM.

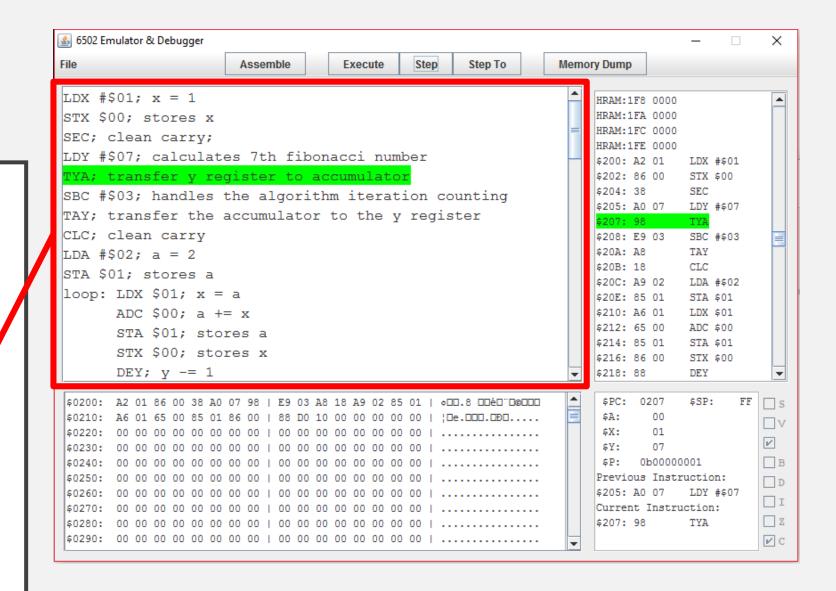

Opcodes and values are displayed for instructions, and their assembly translation is also shown and highlighted at each step.

The user can type, import, or copy and paste standard 6502 assembly into this window.

Once assembled, the currently executed line will be highlighted as the program gets ran.

All programs must be assembled, before any execution commands can be given.

Execute will fully run the program.

Step will run one cycle of the processor.

Step to will allow for a label to be chosen, and the processor will execute to there.
